Overview

- Experimentally, Kh(L) has an abundance of torsion, only some of which we can explain.
- In almost all examples, Kh(L) contains 2-torsion.
- ▶ Torsion of order other than 2 appears, but is much more rare.

Motivating conjecture

Conjecture (Shumakovitch)

Let L be any prime link other than the unknot or the Hopf link. Then Kh(L) contains 2-torsion.

- The conjecture implies that Khovanov homology is an unknot detector.
- Kronheimer and Mrowka (2010) proved Khovanov homology is an unknot detector using gauge theory.

• The conjecture is known to be true in many cases.

Some more conjectures

Conjecture (Przytycki - Sazdanović)

- The Khovanov homology of a closed 3-braid can have only 2-torsion.
- The Khovanov homology of a closed 4-braid can have only 2-torsion or 4-torsion.
- The Khovanov homology of a closed n-braid cannot have p-torsion for p > n, where p is prime.

Methods

Some approaches for proving things about torsion in Khovanov homology are:

- explicit construction (Asaeda, Przytycki),
- connections with Hochschild homology (Przytycki),
- connections with chromatic polynomial cohomology (Helme-Guizon, Pabiniak, Przytycki, Rong, Sazdanović), and

spectral sequence arguments (Shumakovitch).

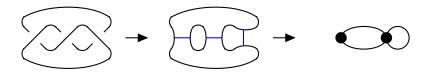

Kauffman states

• Each crossing has an A and a B resolution.

- The collection of simple closed curves in the plane obtained by taking an A or B resolution at each crossing is a Kauffman state.
- ► The all-A state graph G of D has vertices corresponding to the components of the all-A state of D and edges corresponding to the crossings of D.

A 3-crossing unknot

Khovanov and chromatic homology

- ▶ Let *D* be a link diagram, and let *G* be its all-*A* state graph.
- The Khovanov homology of D is Kh(D).
- The chromatic homology of G is H(G).
- Both are bigraded:

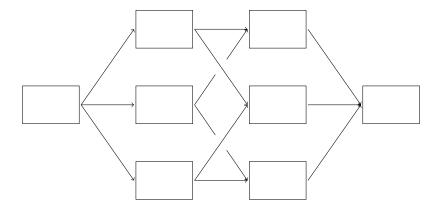

$$Kh(D) = \bigoplus_{i,j} Kh^{i,j}(D) \text{ and } H(G) = \bigoplus_{i,j} H^{i,j}(G).$$

Comparing Kh(D) and H(G)

Theorem (Helme-Guizon, Przytycki, Rong - 2006)

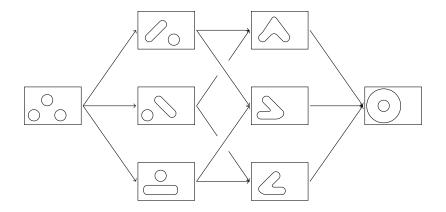

If the length ℓ of the shortest cycle in G is greater than one, then there is an isomorphism between Kh(D) and H(G) in the first $\ell - 1$ supported i-gradings and an isomorphism of Tor Kh(D) and Tor H(G) in the ℓ th i-grading.

Khovanov homology of nonsplit alternating links

- Let *L* be a nonsplit alternating link.
- (Lee) $Kh(L; \mathbb{Q})$ lies on two adjacent j 2i diagonals.
- (Shumakovitch) Kh(L) has no torsion other than 2-torsion.

• Kh(L) is determined by the Jones polynomial of L.

The chromatic homology

- (Chmutov, Chmutov, Rong) The chromatic homology H(G; Q) lies on two adjacent i + j diagonals.
- (Helme-Guizon, Przytycki, Rong) All torsion in H(G) lies on i + j = v(G) diagonal.
- (L., Sazdanović) The chromatic homology H(G) contains no odd torsion.

A Khovanov homology corollary

Corollary

Let D be a diagram with all-A state graph G. Suppose that the length ℓ of the shortest cycle of G is greater than one. Then Kh(D) has no odd torsion in its first ℓ supported i-gradings.

Odd Khovanov homology Kh'(D) is a categorification of the Jones polynomial due to Ozsváth, Rasmussen, and Szabó (2007).

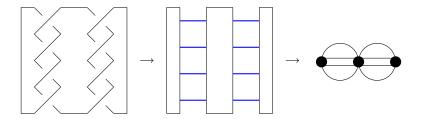

Theorem (L., Sazdanović)

Let D and D' be link diagrams with the same all-A state graph G. Suppose that the length ℓ of the shortest cycle of G is greater than one. Then there is an isomorphism between Kh'(D) and Kh'(D')in the first $\ell - 1$ supported i-gradings and an isomorphism between Tor Kh(D) and Tor Kh(D') in the ℓ th i-grading.

Example $T_{3,4}$

Example $T_{2,4} \# T_{2,4}$

An odd Khovanov corollary

Corollary

Let D be link diagram whose all-A state graph G is planar and has shortest cycle of length ℓ . Then Kh'(D) is torsion free in its first ℓ supported i-gradings.

Proof.

Since *G* is planar, there is an alternating diagram D' whose all-*A* state graph is *G*. Because D' is alternating, its odd Khovanov homology is torsion free (ORS-2007). The result follows from the partial isomorphism proved earlier.

Maximum girth

Define the A-girth of L to be

 $g_A(L) = \max\{ girth(G) \mid D \text{ is a diagram of } L\},\$

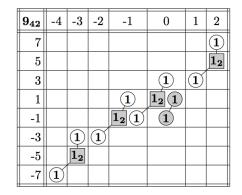

where G is the all-A state graph of D and girth(G) is the length of the shortest cycle of G.

- L is adequate if both g_A(L) and g_A(L) are greater than one, and L is semi-adequate if one of g_A(L) or g_A(L) is greater than one.
- Large girth simplifies formulas for the head and tail of the colored Jones polynomial.

Khovanov upper bound on girth

Suppose that the Khovanov homology of L lies on more than 2 diagonals. Let m be the difference between the first *i*-grading on which a third diagonal supports Kh(L) and the first *i*-grading on which that Kh(L) is supported. Then $g_A(L) \leq m$.

Example 9₄₂

 $g_0(L) \leq 4$

Questions

- Can we show that H(G) contains only 2-torsion?
- How can we generate odd torsion in Kh(L)?
- What does torsion in Kh(L) tell us about the link?
- Can we explain the difference in torsion in Kh(L) and Kh'(L)?
