#### President Abraham Lincoln

"He studied and nearly mastered the Six-books of Euclid (geometry) since he was as member of Congress. He began a course of rigid mental discipline with the intent to improve his faculties, especially his powers of logic and language. Hence, his fondness for Euclid, which he carried with him on the circuit till he could demonstrate with ease all of the propositions in the six books; often studying far into the night, with a candle near his pillow, while his fellow-lawyers, half a dozen in a room, filled the air with interminable snoring."

from Short Autobiography of 1860

What is Euclid about? Why was Lincoln so interested?

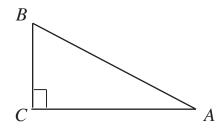

What is the Pythagorean Theorem (PT)?

$$a^2 + b^2 = c^2.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○三 のへぐ

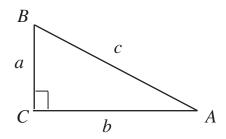

Such notation would only be common after the time of René Descartes (1596-1650).

Begin with a **right triangle**.

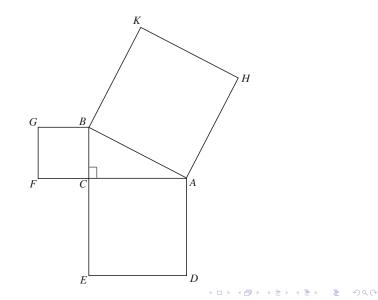

The Pythagorean Theorem. For a right triangle  $\triangle ABC$  with right angle at C, the squares on the legs sum to the square on the hypotenuse.

This is a matter of area. It was Leonard Euler (1707–1783) who introduced the notation for which the length of the side opposite a vertex is labeled by the lower case version of the vertex.

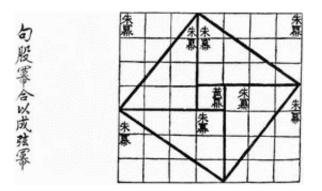

In area we would write  $a^2 + b^2 = c^2$ .

#### The Pythagorean Theorem But Euclid would think:

The right-angle property was known in special cases. The Babylonians and Egyptians knew of the 3-4-5 triangle as a construction idea. They had the *rope-stretchers*.

In a Chinese classic *Chou Pei Suan Ching* (ca. 250 B.C.E.) there is a diagram that demonstrates the 3-4-5 triangle.

How did the Pythagoreans know the Pythagorean Theorem?

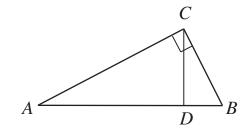

Perhaps proportionality. Recall:

Two triangles are similar if they have the same interior angles.

The sum of the interior angles of a triangle is two right angles  $(180^\circ)$

# Proof by proportionality

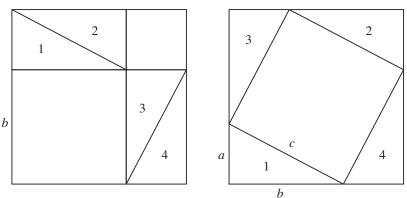

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 - のへで

# Proof by proportionality

$$\frac{y}{a} = \frac{x}{b} = \frac{a}{c}$$
 and  $\frac{x}{a} = \frac{c-y}{b} = \frac{b}{c}$
